E4 uses efficient techniques for the algebraic manipulation required in dealing with questions involving polynomials

Part	Solutions	Marking Guidelines
(a) (i)	Roots are α, β, α + β. $\Sigma\alpha = 2\alpha + 2\beta = -\left(\frac{-16}{32}\right) = \frac{1}{2} \qquad \therefore \alpha + \beta = \delta = \frac{1}{4}$	(a)(i) **2 Marks** ~ Correct solution. **1 Mark** ~ Makes significant progress towards the solution (Uses correct sum)
(ii)	Test $P\left(\frac{1}{4}\right) = 0 \quad (4x-1)$ is a factor. The other two roots have $\alpha + \beta = \frac{1}{4}$; $\alpha\beta = \frac{-1}{8}$ from sum and product of roots of *P(x)* $\therefore a\left(x^2 - \frac{1}{4}x - \frac{1}{8}\right) = 0$ $8x^2 - 2x - 1 = 0$ $\therefore P(x) = (4x-1)(4x+1)(2x-1)$	(a) (ii) **2 Marks** ~ Correct factorisation. **1 Mark** ~ Makes significant progress towards solution
(b)	Real coefficients. So 2−*i* is also a root. $2 + i + 2 - i = 4 \qquad (2+i)(2-i) = 5$ So one quadratic factor is: $(z^2 - 4z + 5)$ If the other 2 roots are α, β: $4 + \alpha + \beta = 5 \rightarrow \alpha + \beta = 1$ $5\alpha\beta = -10 \rightarrow \alpha\beta = -2$ $\therefore P(z) = (z^2 - 4z + 5)(z^2 - z - 2)$	(b) **2 Marks** ~ Correct solution. Must be quadratic factors. **1 Mark** ~ Makes significant progress towards the solution (One correct quadratic factor)
(c)	$P(2) = 0 \rightarrow 4a + 2b = -44$ $P'(2) = 0 \rightarrow 4a + b = -32 \qquad \therefore a = -5 \qquad b = -12$	(c) **2 marks:** Correct solution **1 Mark** ~ Significant progress towards solution.
(d)	$P(x) = Q(x)(x-2)(x+3) + ax + b$ $P(2) = 2a + b = -7$ $P(-3) = -3a + b = 3 \qquad \therefore a = -2 \qquad b = -3$ Remainder = $-2x - 3$	**(d) 2 Marks** ~ Correct remainder . **1 Marks** ~ Makes significant progress towards the solution.
(e) (i)	$(1+i)^2 - bi(1+i) + c = 0$ $(2-b)i + b + c = 0i + 0. \qquad \therefore b = 2 \;\; c = -2$	**(e) (i) 2 Marks** ~ Correct solution. **1 Mark** ~ Makes significant progress towards solution(substitution completed.)
(ii)	Sum of roots = *bi* =2*i* So, other roots = $2i - (1+i) = i - 1$	(e) (ii) **1 mark**: correct answer.
(f)	$P(x) = x^4 - 5x^3 - 9x^2 + 81x - 108$ $P'(x) = 4x^3 - 15x^2 - 18x + 81$ $P''(x) = 12x^2 - 30x - 18 = 6(2x+1)(x-3)$ Possible triple roots are *x*=3, -½ $P\left(-\frac{1}{2}\right) \neq 0; P(3) = P'(3) = P''(3) = 0$ Product of roots = −108, so solutions are: $x = 3, -4$	(f) **2 marks**: Correct roots with justification. **1 mark**: Significant progress towards correct solution.

E2	(b) In ΔAMC and ΔANH $\angle AMC = \angle ANH = 90°$ ($AM \perp BC$ and BN $\perp AC$ since AM and BN are altitudes of ΔAMC and ΔANH) $\angle MAC = \angle HAN$ (common angle to ΔAMC and ΔANH) $\therefore \Delta AMC \parallel\!\mid \Delta ANH$ (equiangular) $\therefore \angle ACB = \angle AHN$ (corresponding angles in similar triangles, $\Delta AMC \parallel\!\mid \Delta ANH$, are equal) Also, $\angle AHN = \angle BHM$ (vertically opposite angles are equal) $\angle BDA = \angle ACB$ (angles at the circumference on the same arc AB are equal) Now, In ΔBMD and ΔBMH $\angle BDA = \angle BHM$ (from above, i.e. $\angle BDA = \angle ACB = \angle AHN = \angle BHM$) $\angle BMD = \angle AMC = 90°$ (vertically opposite angles equal) $\angle BMH + \angle BMD = 180°$ (angle sum of straight angle, $\angle BMH + 90° = 180°$ $\quad$ $\angle AMD$, is 180°) $\angle BMH = 90°$ $\therefore \angle BMD = \angle BMH = 90°$ MB is common $\therefore \Delta BMD \equiv \Delta BMH$ (AAS) $\therefore HM = MD$ (corresponding sides of congruent triangles, $\Delta BMD \equiv \Delta BMH$, are equal) Note: There are other solutions that were accepted as well.	3 marks for complete correct proof with correct reasoning 2 marks for substantial working with correct reasoning that could lead to a correct proof with only a minor error 1 mark for some substantial working with correct reasoning that could lead to a correct proof
